# “New” AI

- unlike GOF AI (which focus on universal mechanisms of logical derivation) “New” AI prefers to employ various specific (ad-hoc) mechanisms and look for mechanisms how to put them together to generate adequate global behavior.

# Postulates of “New” AI

- (Principle of situated system)
- Embodiment
- Emergence
- Interaction
- Hierarchy

# Situated system

- It is designed to not operate under general conditions but under a set of specific conditions
- Former versions can work for a smaller set, later (modified) versions for bigger set
- We do not build one universal handler of general outside conditions; various states of environment have to be handled by various different modules specialized to particular cases. Thus once we succeed thanks to one module, some other time due to activity of another one

# Embodiment

- We do not split design from implementation
- We design having a prototype in hand
- After each increment or modification we have possibility to test on the prototype what he have exactly done and we have chance to correct it until all required tests are passed

# Emergence

- System behavior is a result of interaction among its units
- Sometimes relationship between the two can be hidden to developer; he is not able to predict it, but he is able to test it and then find its explanation

# Interaction

Intelligence can emerge on system which has no cognitive modules due to

- interaction among its units
- its interaction with dynamic environment

# Exhausting of intelligence from environment

- snail Litorino (dies in aquarium, survives in sea)

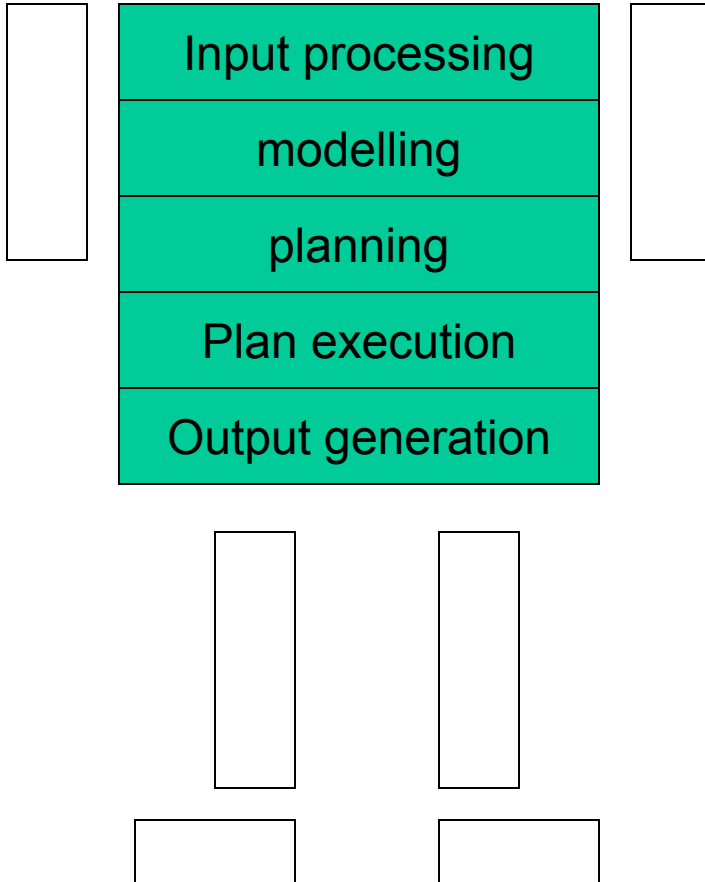

# Hierarchy

- System is developed incrementally from bottom to up
- We start with simpler layers and sequentially add more difficult ones (biomimetic metaphor)
- Risk: we can get to situation that we are not able to provide any further reasonable increment
- Profit: integration of implemented parts cannot fail
- The later levels can employ and affect the former ones

# Decomposition

- By function – to layers which collect modules having similar code, layers create a pipeline
- By activity – to layers which collect modules which are responsible for a particular ingredient of global behavior, layers operate in parallel (preferred)

by function

by activity

# Subsumption

How can a later layer employ and affect a former layer ?

- wire-taping
- inhibition
- suppression

# Wiretapping

- A later layer undertakes data which flow between modules in a former layer

# Suppression

- A later layer overwrites data which flow between modules in a former layer

# Inhibition

- A later layer erases data and thus stops flow between modules in a former layer

# An example

**Control system of mobile robot which has to find a ball in environment with walls, doors, passages, furniture ...**

# Sensors and actuators

detection of the closest obstacle

**Forward/Backward movement and left/right rotation**

Detection of ball

# Design of activities

---

**STOP** – Stop at ball

---

**EXPLORE** – Exploration of space

---

**WANDER** – Random wandering

---

**AVOID** – Avoiding obstacles

---

# AVOID

Anytime we try to go forward

# AVOID

Sonar creates a map of distances to the nearest obstacles in individual sections of space

# AVOID

When there is a danger of bump,  
Collide stops robot

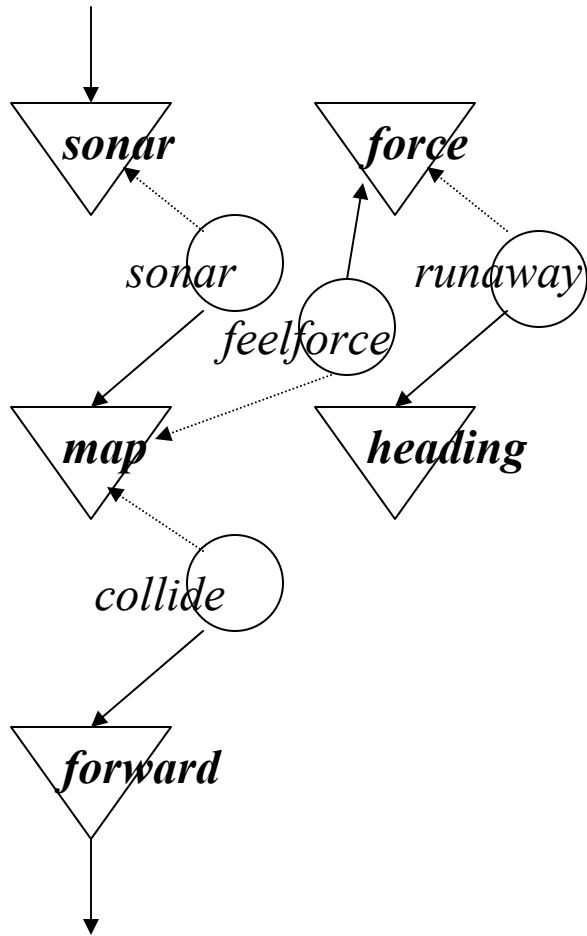

Thus robot goes ahead until it  
reaches and obstacle, then stops.

# AVOID

Feelforce evaluates the most dangerous (relative) direction of movement

# AVOID

Runaway proposes to turn  
somewhere else

# AVOID

Turn stops and turn to the proposed direction

# AVOID

Concern that turning has a feedback to content of map and consequentially to heading. More turn performed, less turn required.

# AVOID

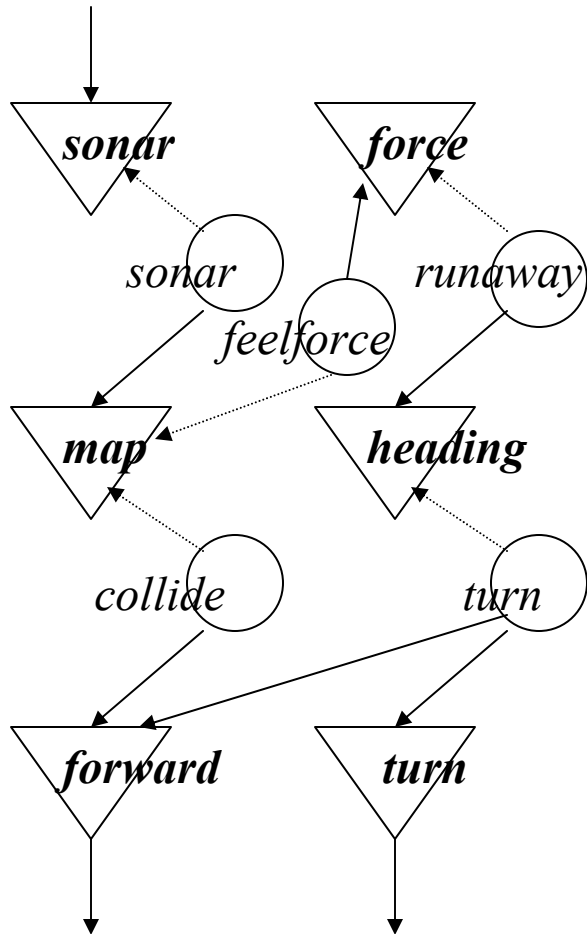

Thus robot go ahead until reaches an obstacle. Then it turns and then follows straightforward. Again turns, again go ahead, repeatedly.

It easily gets on a cyclic path.  
However it is enough for AVOID.

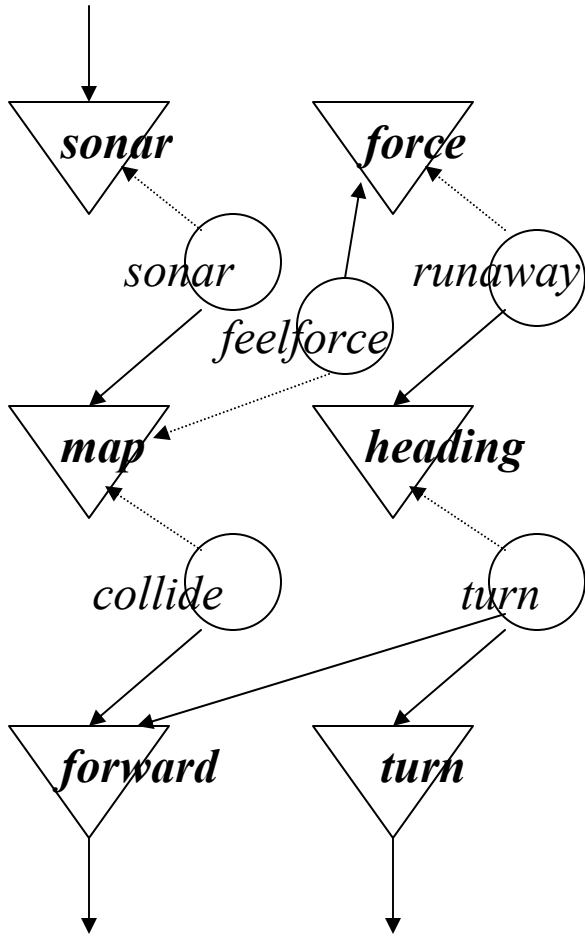

AVOID is finished.

# AVOID

Now it is interesting that by development of avoiding static obstacles we have got also running away from moving objects. (Sometimes we call such situation as emergence)

# AVOID

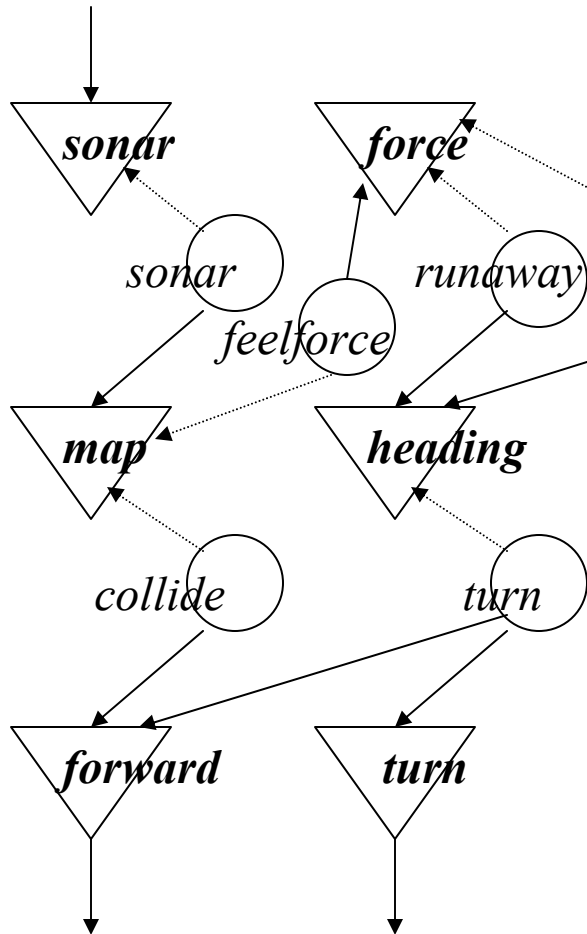

WAN  
DER

Now we would like to get the robot from the cyclic paths by an occasional random movement

Therefore wander  
sometimes propose a  
turn

# AVOID

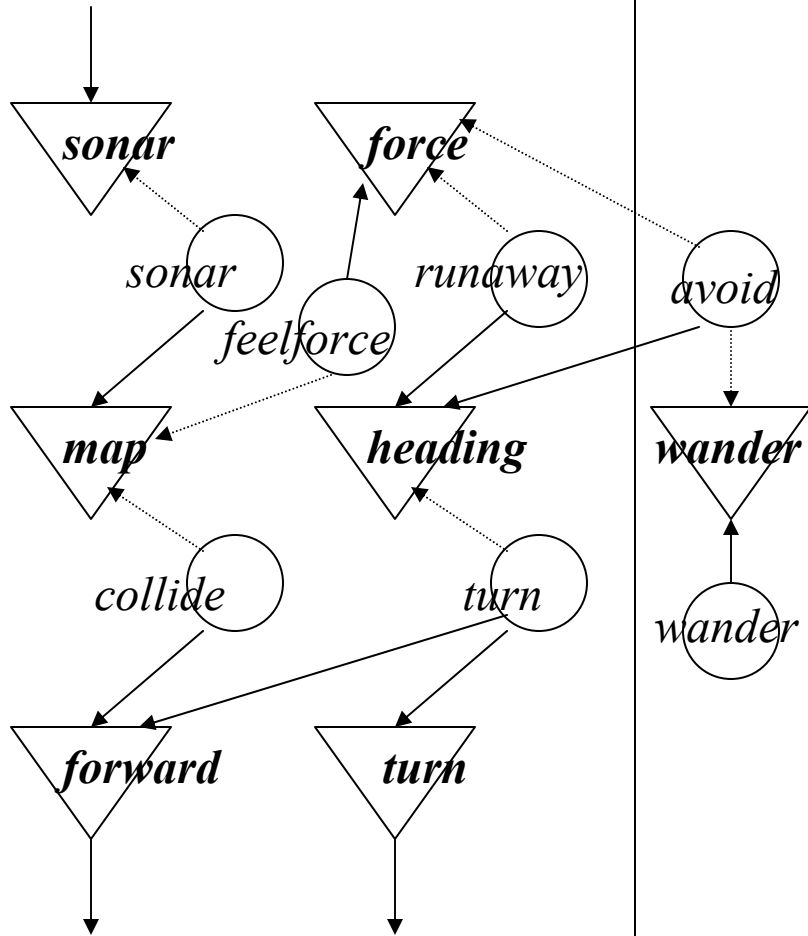

# WAN DER

Agent avoid persuade itself that there is no danger of collision and then overwrite heading by the direction proposed by Wander

Thus we employ avoiding obstacles for random wandering, since Agent Turn use the value as written by agent Heading

# AVOID

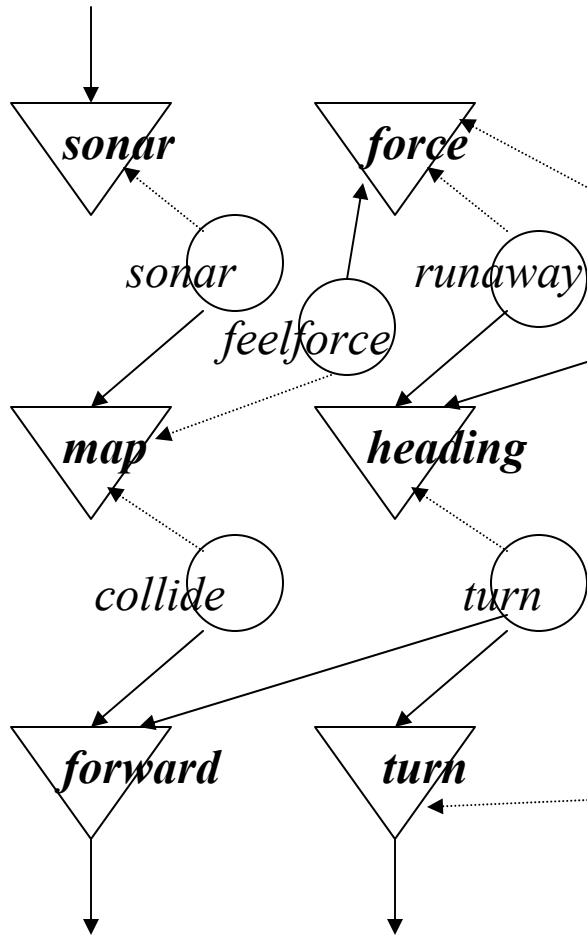

# WANDER

Now robot avoids obstacles but its movement is unpredictable.

But it stays in quite a small area.

# AVOID

# WANDER

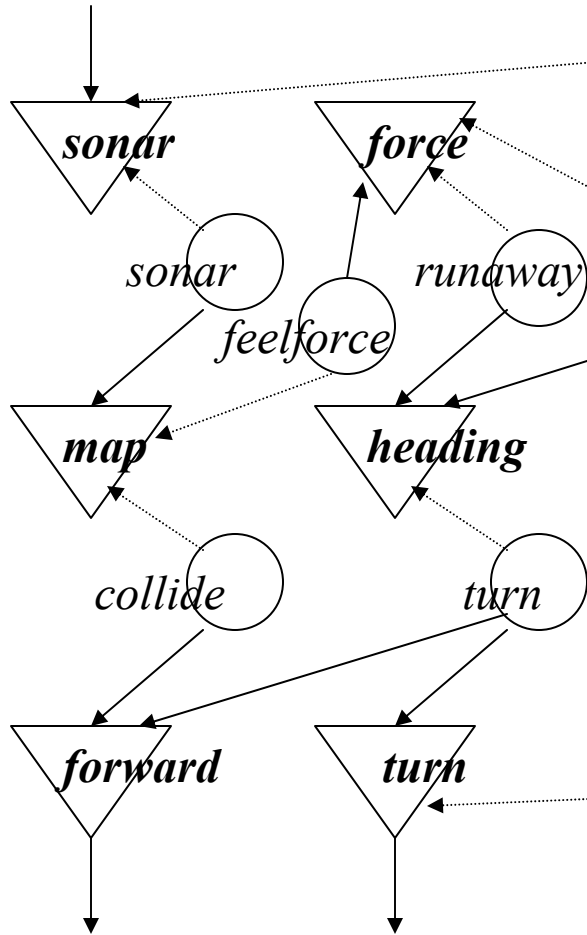

# EXPLORE

whenlook observes this staying and it persist for too long, generate a command to move elsewhere

# AVOID

# WAN DER

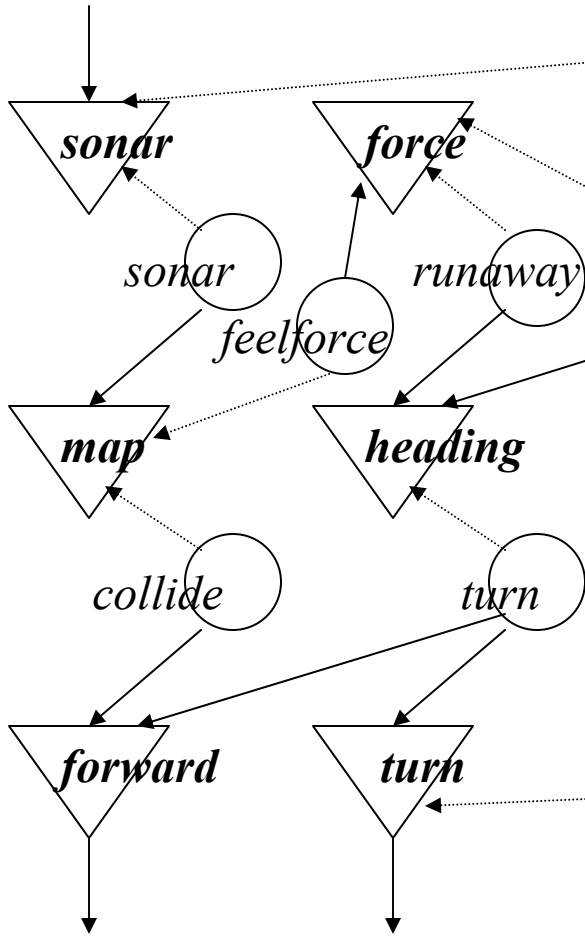

# EXPLORE

Stereo is  
looking for  
possibility  
of free  
movement

# AVOID

# WANDER

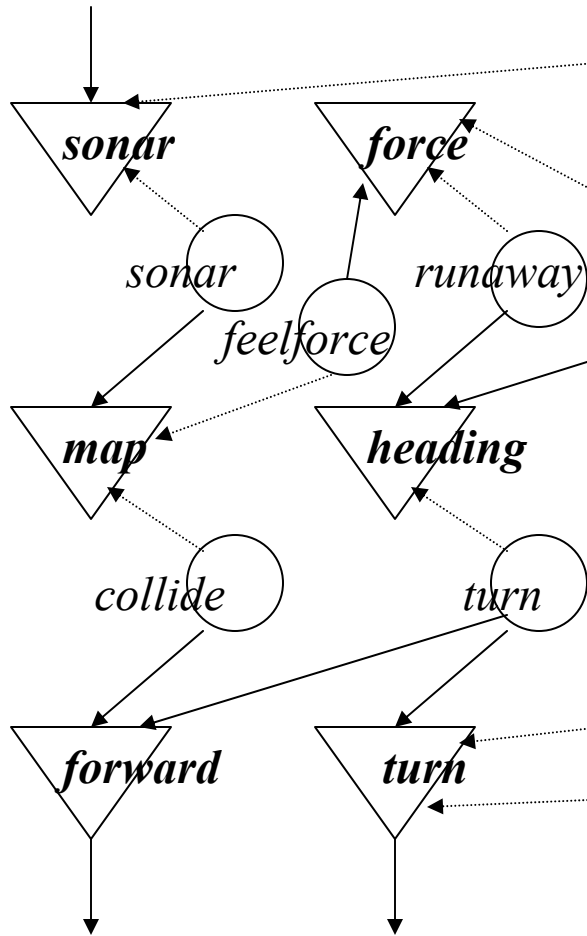

# EXPLORE

# Path chooses a direction of exploration

# AVOID

# WANDER

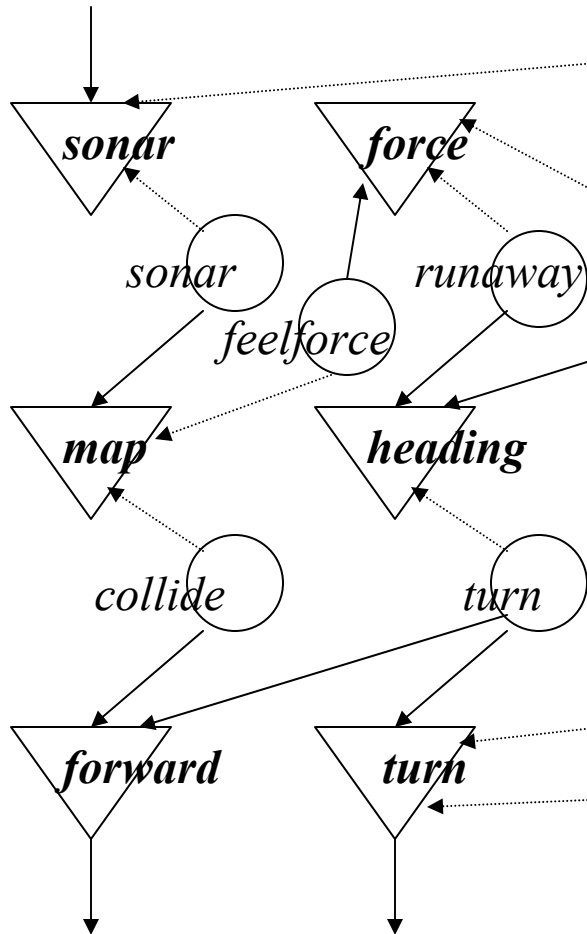

# EXPLORE

This is only a relative direction, so we need to estimate difference to calculate absolute directions

# AVOID

# WANDER

# EXPLORE

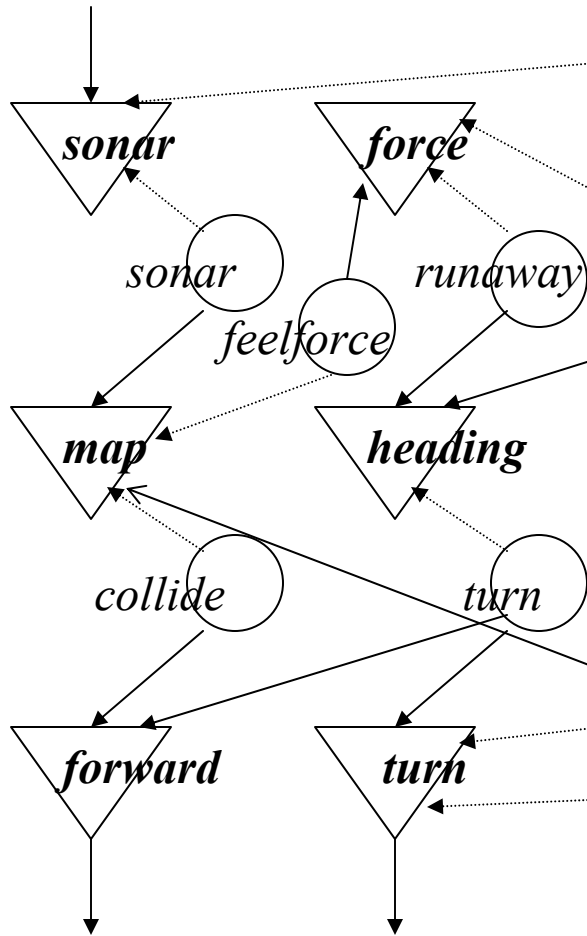

Pathplan calculate a turn which has to be provide to follow the absolute direction of exploration and propose it as a random movement (which is random at all)

# EXPLORE

# AVOID

# WANDER

# EXPLORE

# STOP

When we have found ball, we stops the robot by emulation obstacles around it

# Criticism

- Inaccessibility of internal state
- Disruption of levels of competence
- Data fusion

## Alternative solutions

- fine-grained alternative (Rosenblatt, Payton)
- Behavioral systems (Arkin)

Thank you for your attention !
